

Histology of the Nervous System

Divisions of the Nervous System

- **Anatomically**

 - CNS: Brain and Spinal cord**

 - PNS: Nerves and Ganglia**

- **Histologically**

 - Nerve cells**

 - Glial cells**

Development of the Nervous System

- During early development, the embryo is formed of three germ layers

Ectoderm

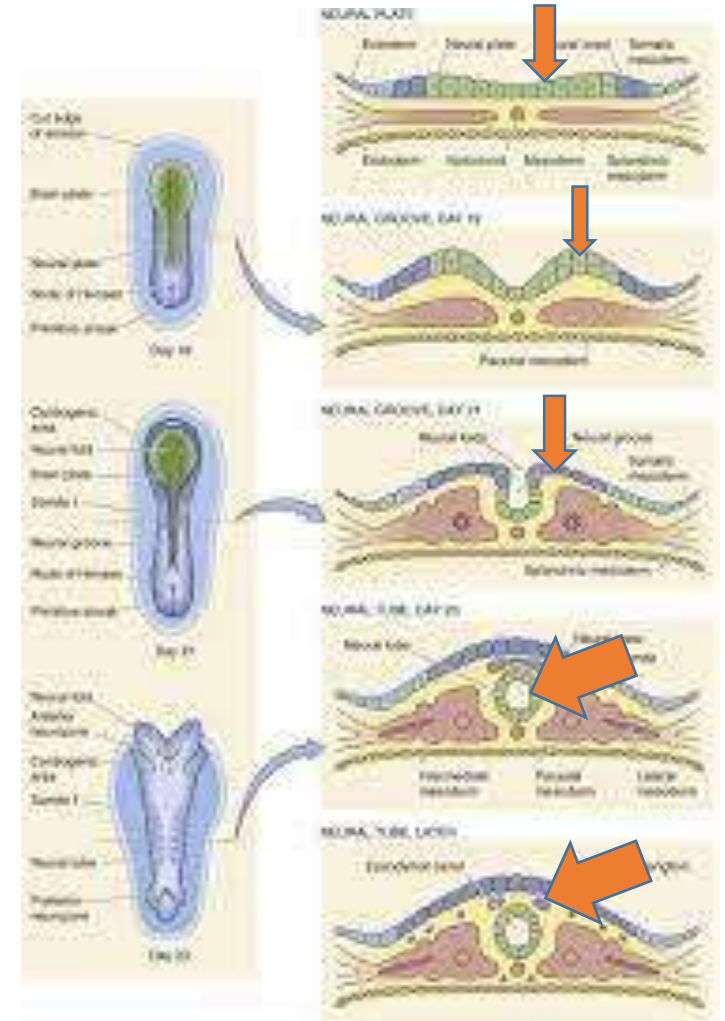

Mesoderm

Endoderm

- Ectoderm forms most of the nervous system

Neural tube

Neural crest

Divisions of the Nervous System

- The neuron is the structural and functional unit of the nervous system
- Functions:
 - Reception, Processing, and Transmission of nerve stimuli
 - Triggering certain cell activity
 - Release of neurotransmitters
- Parts:
 - Cell body (Perikaryon)
 - Dendrites
 - Axon- Arorization, Bouton
- They vary in shape
- They vary in size (5-150 μm)

Classification of Neurons

- **Morphologically:**

Multipolar

Bipolar

Unipolar (Pseudounipolar)

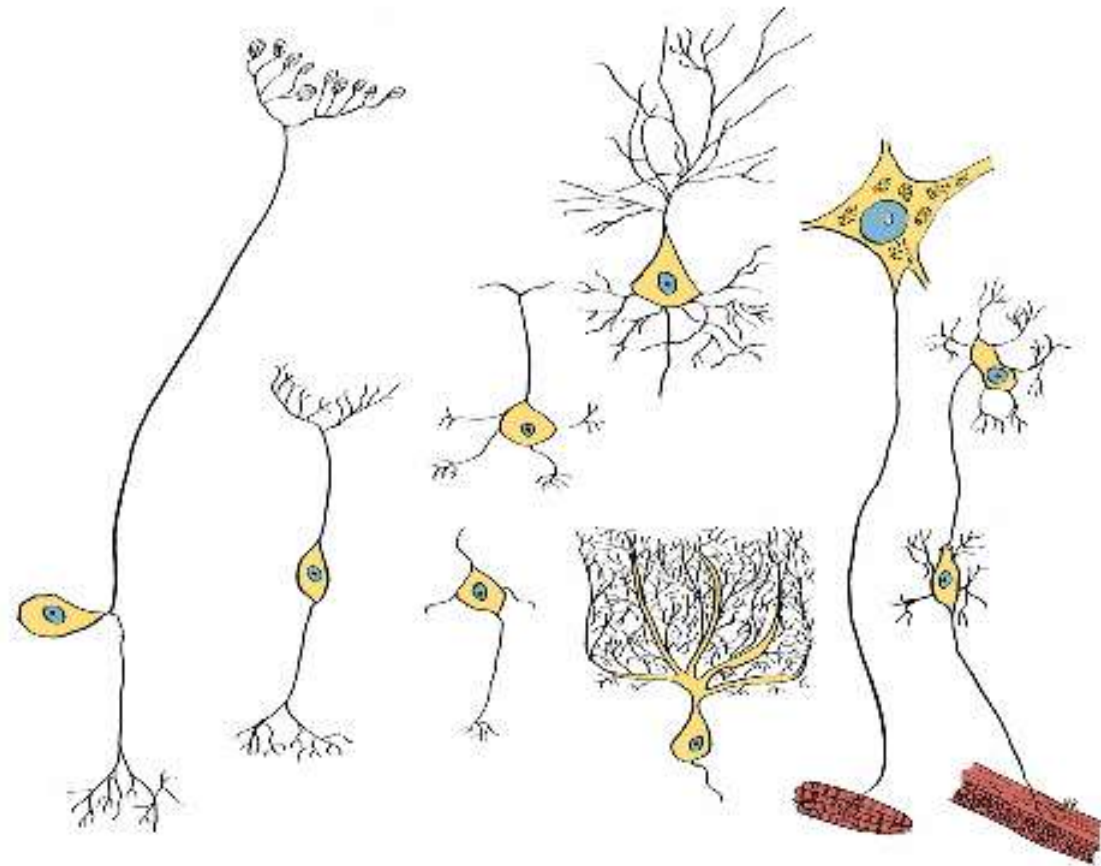

- **Functionally:**

Motor (Somatic and Autonomic)

Sensory

Interneurons

Structure of the Neuron

Cell body: the trophic center

Dendrites: Receive and process signals

Many arborizations

Dendritic spines

Dendritic transport

Axon: Structure

Anterograde flow-

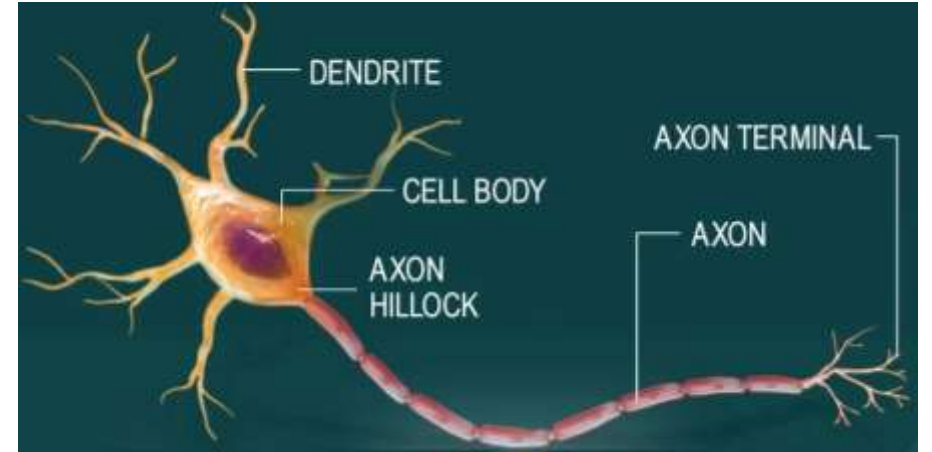

Slow for proteins and actin,tubulin

Medium for mitochondria

Fast for neurotransmitters,AA, vesicles

Retrograde flow

Motor proteins- Kinesin and Dyenin

Synapses

Types:

Chemical and Electrical (Acetylene Choline)

Excitatory and Inhibitory (Na and Cl channels)

Symmetrical and asymmetrical

Glial Cells

- Oligodendrocytes
- Astrocytes (Fibrous and Protoplasmic)
- Ependymal cells
- Microglia
- Schwann cells
- Satellite cells

- **Blood Brain Barrier (BBB)**

Longitudinal section of blood vessel

Types of Neuroglia

<i>Central Nervous System</i>		<i>Peripheral Nervous System</i>
<p>Ependymal cells</p>	<p>Oligodendrocytes</p>	<p>Satellite cells</p>
<p>Astrocytes</p>	<p>Microglia</p>	<p>Schwann cells</p>

Central Nervous system (Cerebrum)

- White matter
- Gray matter
- Alzheimer Disease

Central Nervous system (Cerebellum)

- White matter
- Gray matter

Molecular layer

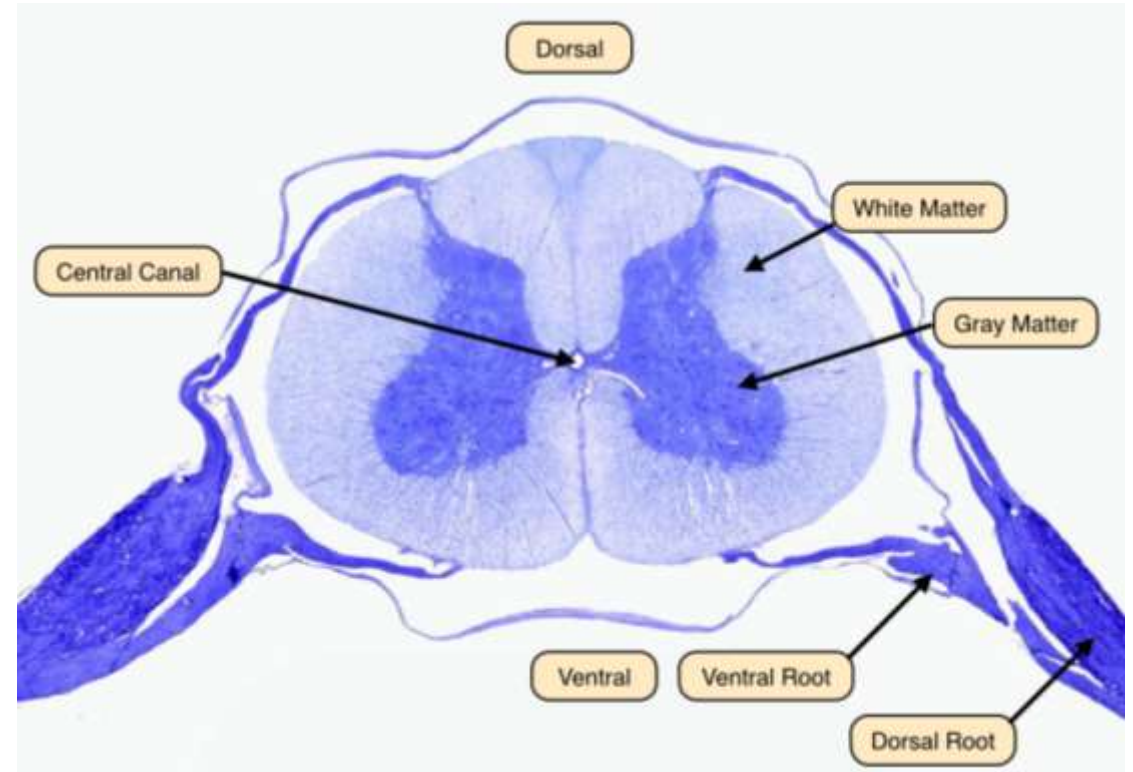

Purkinje layer

Granular layer

Central Nervous system (Spinal Cord)

- White matter
- Gray matter
- Anterior horn
- Posterior horn
- Intermediate horn
- Central canal

Peripheral Nervous System

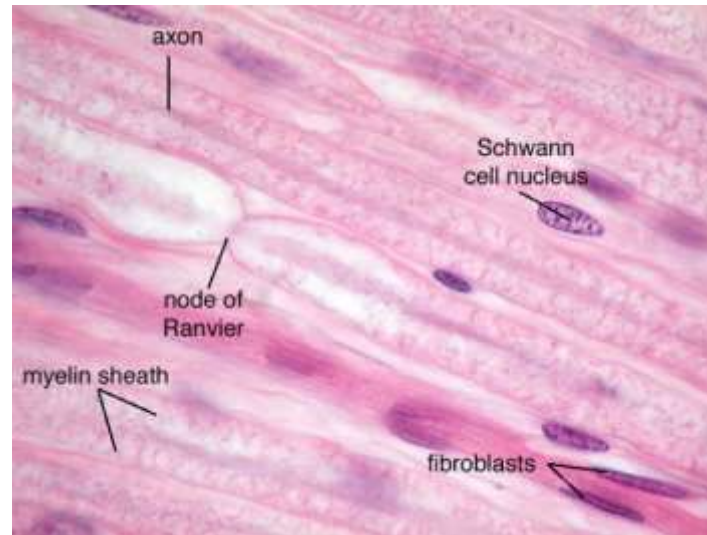

Consists of Nerves, Ganglia, and nerve endings

Nerves

- Nerve fibers

Myelinated with Node of Ranvier

Unmyelinated

- Myelinated fibers
- Multiple sclerosis

Nerve Organization

- In the peripheral nervous system, nerve fibers are grouped in bundles to form nerves
- Consists of nerve fibers

Endoneurium

Perineurium

Epineurium

Ganglia

- **Structure:**
Cells, axons, Satellite cells
- **Types:**
Sensory
Autonomic

Regeneration and Degeneration

- **Destroyed processes and nerve fibers can regenerate to a certain extent.**
- **The dead neuron will not affect neurons in the vicinity except if one neuron is in contact with a dead one
(Transneuronal degeneration)**

Axon Transection

1. The proximal segment regenerates while the distal one degenerates
2. Perikaryon undergoes chromatolysis
3. The proximal segment first degenerates and then starts regeneration
4. Distally, axon and myelin sheath degenerate and are removed by macrophages except for the surrounding Schwann cells

Axon Transection Cont.,

5. Schwann cells proliferate giving solid cellular columns which direct the sprouting nerve
6. Proximal end grows and branches giving many filaments that progress in the direction of Schwann cell columns
7. Neuroma: a mass of growing nerve tissue fails to meet the distal segment

Clinical Application

Multiple Sclerosis and Guillain-Barre syndrome

Nerve Tissue Tumors

Medulloblastoma

Glioma (Astrocytoma)

Schwannoma
