CLASSIFICATION OF AMINO ACIDS

Nebras Melhem

The building blocks of
amino acids

Introduction

→ 4 imp atoms that form proteins
→ most abundant in life

oxygen
carbon
nitrogen
hydrogen

Protein: Organic compounds with high molecular weight formed from amino acids

- Composed of carbon, hydrogen, oxygen, nitrogen +/- sulphur
- Nitrogen forms appx 16% of their weight (characteristic for proteins)

Besides water, proteins are the most abundant molecules in all known forms of life. Proteins are the most diverse class of biological molecules, making up everything from enzymes and hormones to antibodies.

- About 70% of your body weight is water, and about 17% is protein.

Introduction

→ Amino-acids nearly have a function in everything in our bodies.

Amino acids participate in the biosynthesis of: [amino acids Not proteins]

Purines

Pyrimidines

Urea

هي neurotransmitter ← amino acid
Histidine و glutamate دي دي

AA form peptides (2-50 amino acids) which have a roles as: [peptides Not proteins]

Hormones

Neurotransmitters

AA form proteins (>50 amino acids) which have a roles as:

Plasma membrane

Hormones

Enzymes

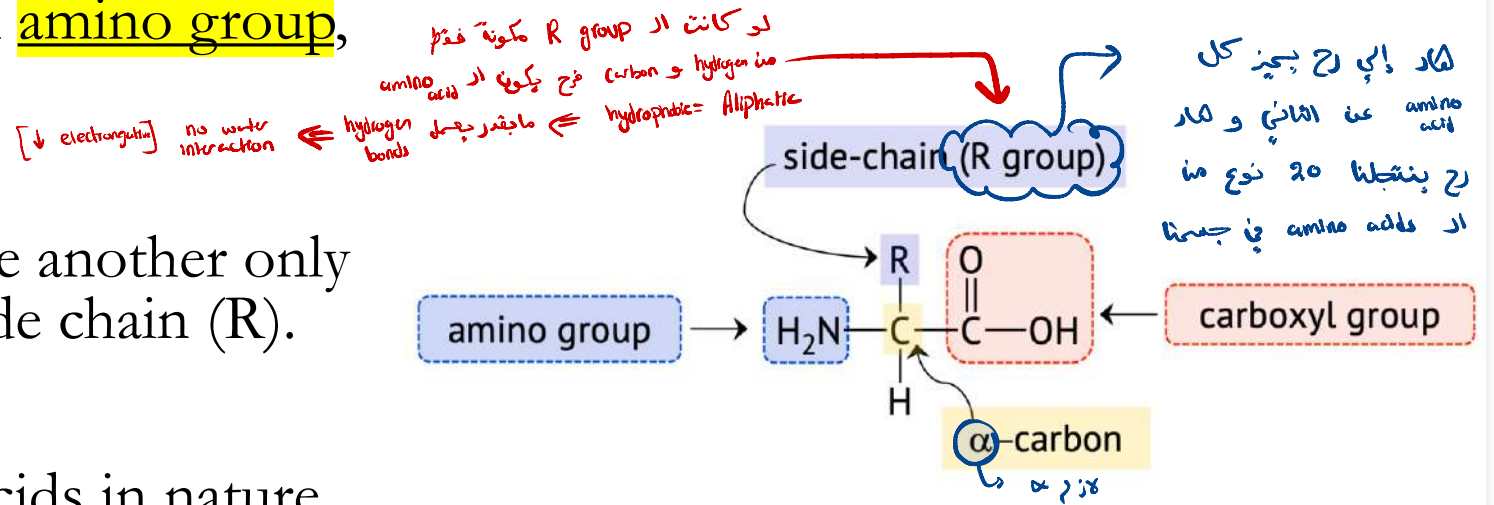

General Structure of Amino Acids

- All amino acids have a **central carbon atom** attached to a **carboxyl group**, an **amino group**, and a **hydrogen atom**.

- The amino acids differ from one another only in the chemical nature of the side chain (R).

- There are hundreds of amino acids in nature, but only 20 are used as building blocks of proteins in humans.

لكن بالطبيعة تم اكتشاف
تقريبا 500

The basic structure of amino-acids.

General Structure of Amino Acids

- The R group is the only part of an amino acid's structure that varies from one to the other; the other parts of the structure are common to all of them.
- R groups are aliphatic when they contain only carbons and hydrogens, which are so similar in electronegativity that they are **nonpolar**—meaning they are **hydrophobic** or can't make hydrogen bonds with water and therefore avoid it.
- Other R groups contain other atoms and can ionize or make hydrogen bonds, so these are **hydrophilic**—they like water.

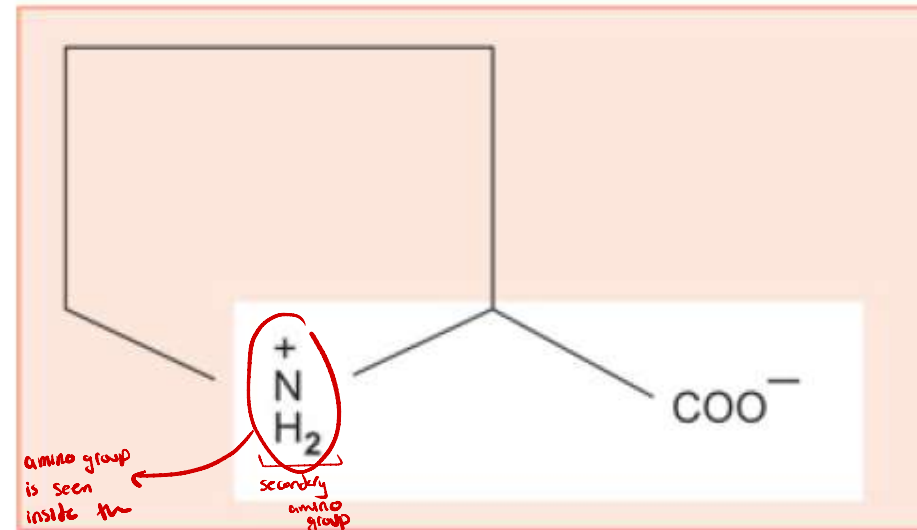

Imino Acid

↳ The only amino acid that has a different structure [in terms of the back bone structure] than the one above.

- Amino acid group not free
- The nitrogen of amino group is seen inside the ring

• **Proline** is an imino acid

↳ From proline, we can biosynthesize proteins.

Structure of imino acid

↓
زيتي ما حكيما تكون non-polar
لما تكون R group فقط مكونة
من C & H

Non-Polar Aliphatic Side Chain

- **Hydrophobic amino acids**, which have R groups that mostly contain carbons and hydrogens, include glycine, alanine, valine, leucine, isoleucine & proline.
- The degree of **hydrophobicity increases steadily from glycine to isoleucine** as the R groups increase in size and complexity.

* no alpha structure *

Valine, Leucine, isoleucine
are considered branched chain
amino acids . . .

§§ Branched chain amino acids

Polar Uncharged R groups

More soluble in water than the non-polar aliphatic group.

Their (R) groups contain neutral polar functional groups, which form hydrogen bonds with water.

- 1- Serine, threonine (contain hydroxyl group)
- 2- Cysteine (contains thiol group)
- 3- Asparagine and glutamine (contain amide group)

Polar, Uncharged R Groups

$\begin{array}{c} \text{COO}^- \\ \\ \text{H}_3\text{N}^+ - \text{C} - \text{H} \\ \\ \text{CH}_2\text{OH} \end{array}$ <p>Serine Ser</p>	$\begin{array}{c} \text{COO}^- \\ \\ \text{H}_3\text{N}^+ - \text{C} - \text{H} \\ \\ \text{H} - \text{C} - \text{OH} \\ \\ \text{CH}_3 \end{array}$ <p>Threonine Thr</p>	$\begin{array}{c} \text{COO}^- \\ \\ \text{H}_3\text{N}^+ - \text{C} - \text{H} \\ \\ \text{CH}_2 \\ \\ \text{SH} \end{array}$ <p>Cysteine Cys</p>
$\begin{array}{c} \text{COO}^- \\ \\ \text{H}_3\text{N}^+ - \text{C} - \text{H} \\ \\ \text{CH}_2 \\ \\ \text{CH}_2 \\ \\ \text{S} \\ \\ \text{CH}_3 \end{array}$ <p>Methionine Met</p>	$\begin{array}{c} \text{COO}^- \\ \\ \text{H}_3\text{N}^+ - \text{C} - \text{H} \\ \\ \text{CH}_2 \\ \\ \text{C} = \text{O} \\ \\ \text{H}_2\text{N} \end{array}$ <p>Asparagine Asn</p>	$\begin{array}{c} \text{COO}^- \\ \\ \text{H}_3\text{N}^+ - \text{C} - \text{H} \\ \\ \text{CH}_2 \\ \\ \text{CH}_2 \\ \\ \text{C} = \text{O} \\ \\ \text{H}_2\text{N} \end{array}$ <p>Glutamine Gln</p>

hydrophobic [non-polar] because sulfur has the same electronegativity as carbon.

Same structure as Asparagine, except here we added CH₂.

Aromatic Side Chains

- A subgroup of the hydrophobic amino acids is the aromatic amino acids, named for the large and quite stable aromatic ring structures in their side chains.
- **Phenylalanine**, is a phenyl ring of 6 carbons attached to an alanine. The R group is hydrophobic. It exhibits some properties of hydrophilic amino acids, but the ring makes it also hydrophobic.
- The largest hydrophobic amino acid is **tryptophan**, which has an R group of 9 carbons and 1 nitrogen in a structure known as an **indole ring**. *Tryptophan is also a component of the neurotransmitter serotonin.*

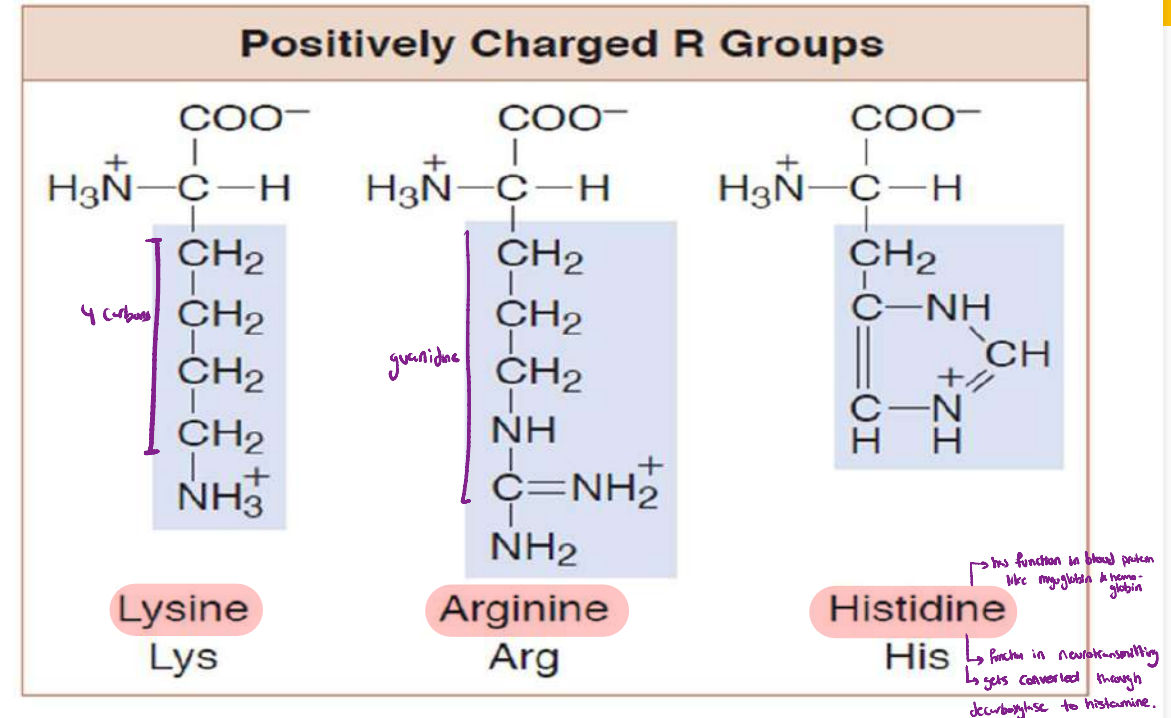

Negatively Charged R Groups

- The acidic amino acids contain carboxyls in their R groups—**aspartic acid** and **glutamic acid**. Ionized forms of these are called aspartate and glutamate.
- Both aspartate and glutamate help cells use protein as an energy source when supplies of sugar run low or when a person goes on a low-carbohydrate diet. In cells, aspartate and glutamate are important in managing ammonia (NH₃), a toxic by-product of metabolism.

Positively Charged R Groups

- The 3 basic amino acids—lysine, histidine, and arginine—are called basic because their R groups accept protons at physiological pH, giving them positively charged R groups.
- **Arginine** plays an important role in the urea cycle as the source of urea – (Guanidine group).
- **Histidine** is important in many enzymes and in the blood proteins myoglobin and hemoglobin.

Glutamine
Gln

Aspartate to Asparagine,

add NH_2 + remove 1 oxygen [decarboxylation]

[Same for glutamate \rightarrow glutamine]

Brain needs glutamate, however glutamate does not cross the blood brain barrier. Glutamine on the other hand can cross blood-brain barrier entering the brain.

Inside the brain, using an enzyme, glutamine converts to glutamate so brain can use it.

- Tryptophan can form serotonin and niacin.
 (neurotransmitter)
 → Vitamin B3
- Valine, leucine, and isoleucine are branched-chain amino acids.
 → epinephrine / nor-epinephrine / dopamine
 < neurotransmitters >

Hydrophilic Amino Acids

- Have side chains that contain O or N atoms; some of the hydrophilic side chains are charged at physiologic pH.
 - The acidic amino acids (**aspartic** and **glutamic acids**) have carboxyl groups that are negatively charged, whereas the basic amino acids (**lysine**, **arginine**, and **histidine**) have nitrogen atoms that are positively charged.
-

Side notes!

معظم لها در يتعتبرون non-polar

- **Tyrosine** can be considered nonpolar or polar because of the ability of the -OH group to form a hydrogen bond.
- **Methionine** can be considered nonpolar or polar because it contains a sulfur.

Optical Activity

- All amino acids except glycine can exist in 2 mirror image forms.
- These differ in the arrangement of the 4 groups around the alpha carbon.
- It's like right and left hands that cannot be superimposed on each other.
- The 2 forms are called stereoisomers: the L form and the D form.
- Glycine is different from all the other amino acids in having an H across from another H, so there's only one form of glycine.

L FORM

D FORM

* تقریباً کل amino acids جسٹنا موجود ہیں ل form

Optical Activity

* جسٹنا ممکن ٹکونا amino acids D form جسٹنا Bacteria

- All chiral compounds, such as amino acids when made apart from cells, have a 50/50 mixture of the D and L forms.
- However, amino acids made in cells for use in protein synthesis are **almost completely in the L form.**

L FORM

D FORM

BASED ON NUTRITIONAL REQUIREMENT

20 amino acids are needed for protein synthesis.

• **Essential:** Those amino acids which cannot be synthesized in the body. Hence these amino acids are to be supplied in the diet. [8] essential amino acids

• **Semi-essential:** Growing children require them in the food, but not essential in adults (ex: Arginine). [2] Semi essential Arginine
histadine

• **Nonessential:** Amino acids which can be synthesized in the body, hence not required in the diet. [10] non-essential

Can't be synthesized in body

"Any Help In Learning These Little Molecules Proves Truly Valuable"

This stands for

Arginine, Histidine, Isoleucine, Leucine, Threonine, Lysine, Methionine, Phenylalanine, Tryptophan and Valine in that order.

Non-essential Amino acids

- The remaining 10 amino acids are non-essential, because their carbon skeleton can be synthesized by the body.
 - The non-essential amino acids are **Alanine, Asparagine, Aspartate, Cysteine, Glutamine, Glutamate, Glycine, Proline, Serine and Tyrosine.**
-

Essential & Non-Essential Amino Acids

Essential Amino Acids:

- Arginine
- Isoleucine
- Histidine
- Leucine
- Methionine
- Lysine
- Phenylalanine
- Tryptophan
- Threonine
- Valine

Non-Essential Amino Acids:

- Alanine
- Arginine
- Asparagine
- Aspartic Acid
- Cysteine
- Glutamic Acid
- Glutamine
- Glycine
- Proline
- Serine
- Tyrosine

يمكن أيضا تصنيف ال amino acids حسب ال metabolic fate
 glucose
 ketone bodies
 لدرج تصنيفها

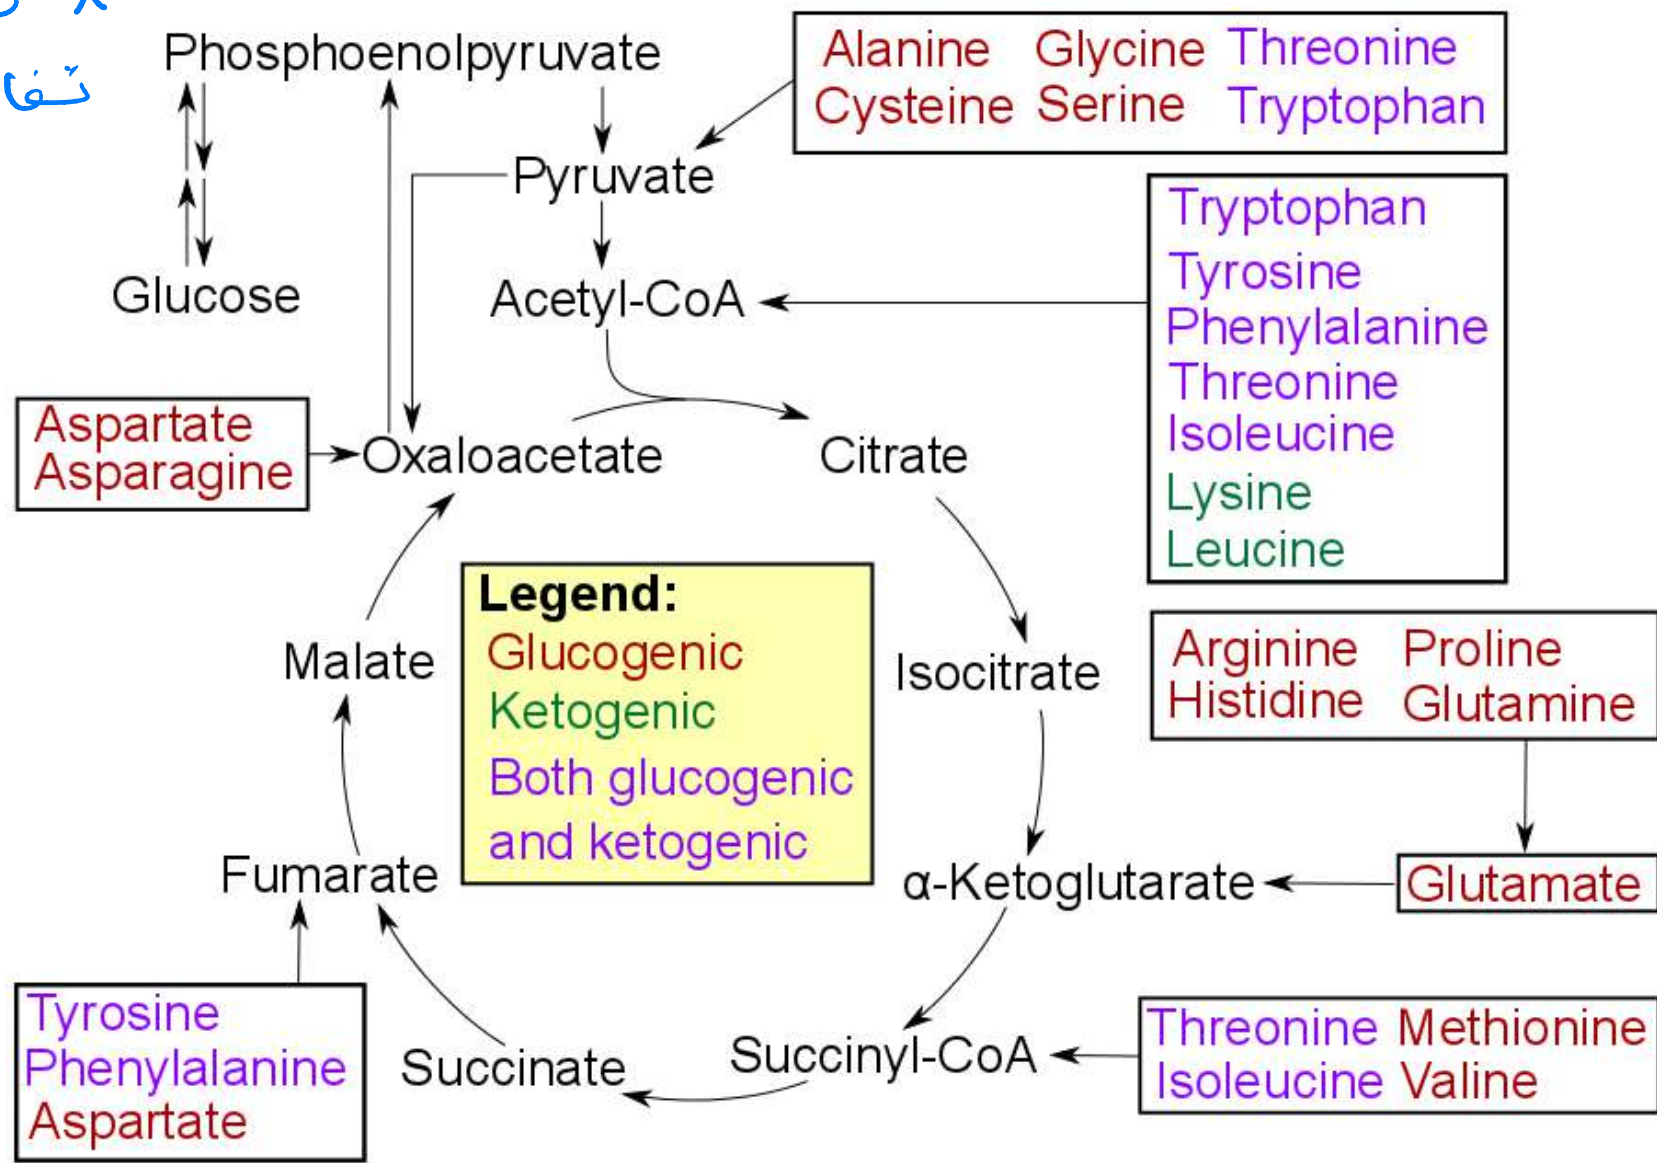

BASED ON METABOLIC FATE

- **Purely ketogenic:** Leucine & Lysine are purely ketogenic because they are converted to ketone bodies
- **Ketogenic and glucogenic:** Isoleucine, Phenylalanine, Tyrosine and Tryptophan are partially ketogenic and partially glucogenic. During metabolism, part of the carbon skeleton of these amino acids will enter the ketogenic pathway and the other part to glucogenic pathway.
- **Purely glucogenic:** All the remaining 14 amino acids are purely glucogenic as they enter only into the glucogenic pathway

PROPERTIES OF AMINO ACIDS

- Solubility: all amino acids are soluble in water.
- However, **cystine** is poorly soluble; that is why excretion of large amounts of cystine in urine (cystinuria) leads to stone formation.
