

# PHYSIOLOGY HAYAT BATCH

done by 8 Scientific Team

lecture no: 35

Figure 6-1. Organization of skeletal muscle, from the gross to the molecular level. E, G, H, and I are cross sections at the levels indicated.

## General Physiology: Edema & Lymphatic system

Rula Bany Bakar  
MD, MSc, PhD

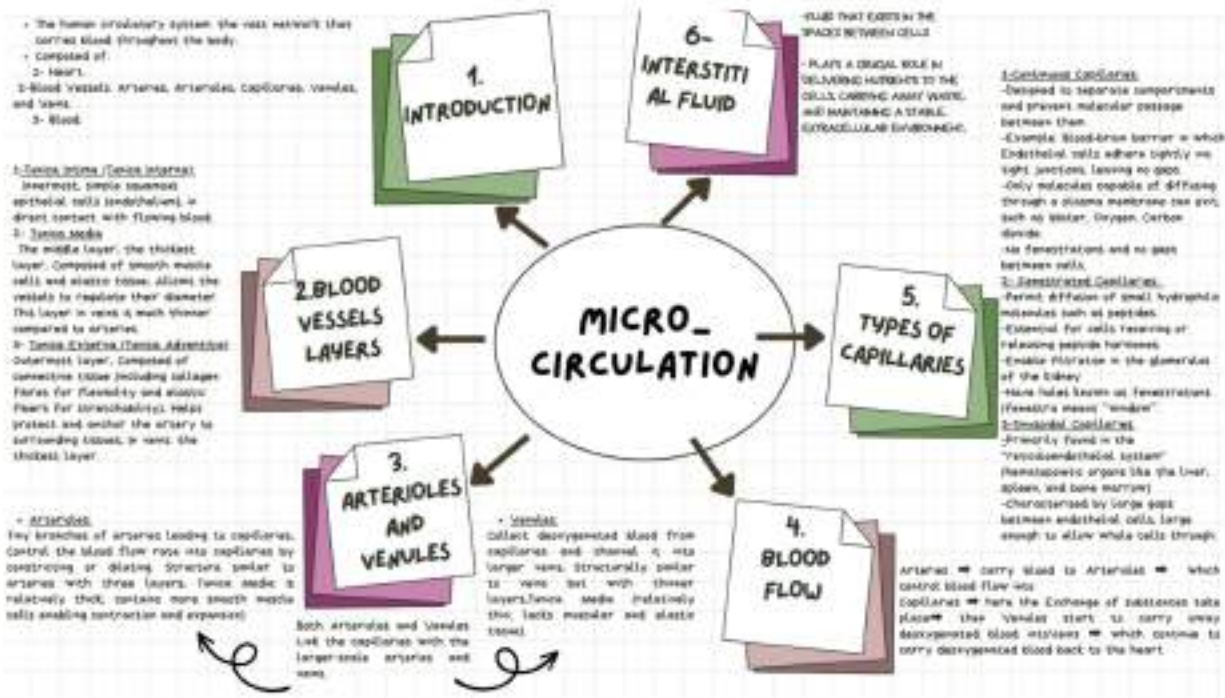

## Objectives:

---

- ✓ Quick Recap for the last lecture.
- ✓ Edema:
  - Definition
  - Causes And Mechanisms:
    - 1- Increased capillary hydrostatic pressure
    - 2- The permeability of the capillary (Represented by K).
    - 3- Decreased capillary oncotic pressure
    - 4- Lymphatic system blockage or breakdown
  - Clinical Examples
- ✓ Lymphatic system:
  - Lymph
  - Lymph Nodes
  - Lymphatic organs
  - Lymphatic vessels
  - Lymphatic system functions.

# Here is quick recap for the last lecture:

# Here is quick recap for the last lecture:

### 1. Simple Diffusion

The process by which solutes are moved along a concentration gradient.  
It does not require the assistance of membrane proteins.  
The exchange of solutes and gases (O<sub>2</sub> and CO<sub>2</sub>) substances directly through the cell membrane of capillaries (O<sub>2</sub>, CO<sub>2</sub>)

### 2. Carrier Proteins

Proteins are generally too large to cross the capillary walls via the gaps between endothelial cells. They are moved across cell membranes by carrier proteins, which are (very membrane-enclosed) just below the cell.

### 3. Bulk Flow

Water-soluble substances (eg. water, ions, glucose, amino acids) that are not lipid soluble can't cross the endothelial cell membranes and diffuse through the narrow clefts between cells.

### EXCHANGE

- That and small solutes move out of the capillary and into the interstitial space
- Caused by hydrostatic pressure (blood pressure)
- Priority occurs at the arterial end of a capillary
- Large substances like proteins, however, are typically too big to be filtered and remain in the capillary

- 90% of filtered fluid is reabsorbed on the venous end
- The remaining 10% of the filtered fluid is returned to circulation via lymphatics

### Starling Law of the capillary

- The components are: forces the capillary compartment (within the capillary lumen) and the interstitial compartment (the space outside the lumen)
- Hydrostatic pressure pushes fluid out of the capillary, while Osmotic pressure pulls fluid in the opposite direction
- Net fluid movement depends on the balance of these four forces: capillary hydrostatic, interstitial hydrostatic, capillary osmotic, and interstitial osmotic
- The balance can be represented by the formula:  $J_v = k [(P_{cap} - P_{int}) - (\pi_{cap} - \pi_{int})]$ , where  $J_v$  is the fluid flow,  $k$  is the permeability factor and  $P_{cap}$  and  $P_{int}$  are the capillary and interstitial hydrostatic pressures, and  $\pi_{cap}$  and  $\pi_{int}$  are the capillary and interstitial osmotic pressures.
- In most cases (except during and obstructive nephrosis) the hydrostatic forces are negligible, simplifying the equation to consider only capillary pressures.

The balance between diffusion and perfusion is known as Starling's Law of the capillary

$$J_v = K_f [(P_c - P_i) - (\pi_c - \pi_i)]$$

### Reabsorption

- That and small solutes (fluid and small solutes) are drawn back into the capillary
- Caused by the osmotic pressure created by the proteins that were not filtered out.
- Priority occurs at the venous end of the capillary

## Edema: Definition

---

- Definition: An increase in interstitial fluid volume.
- It can be localised or generalised.
- It can be pitting and non-pitting.
- Edema can form when there are:
  1. Increased filtration
  2. Decreased reabsorption
  3. Impaired lymphatic drainage: when the volume of interstitial fluid (due to filtration out of the capillaries) exceeds the ability of the lymphatics to return it to the circulation
  4. increase the permeability of capillaries

## Edema: Causes

---

- ☐ To understand different causes of edema let's have another look at the Sterling equation:

$$J_v = K_f [(P_c - P_i) - (\pi_c - \pi_i)]$$

- ☐ The main factors in this equation are:

- ❖  $K_f$  is the water permeability of the capillary wall. It varies among different types of tissues, depending on the anatomic characteristics of the capillary wall.
- ❖ The hydrostatic pressure (filtration process).
- ❖ The Oncotic pressure (reabsorption process).

## Edema: Causes

---

- 1- Increased capillary hydrostatic pressure** → filtration → high Systolic Blood Pressure > 160
- 2- The permeability of the capillary (Represented by K).**
- 3- Decreased capillary oncotic pressure**
- 4- Lymphatic system blockage or breakdown**

## Edema: Causes

### 1- Increased hydrostatic pressure:

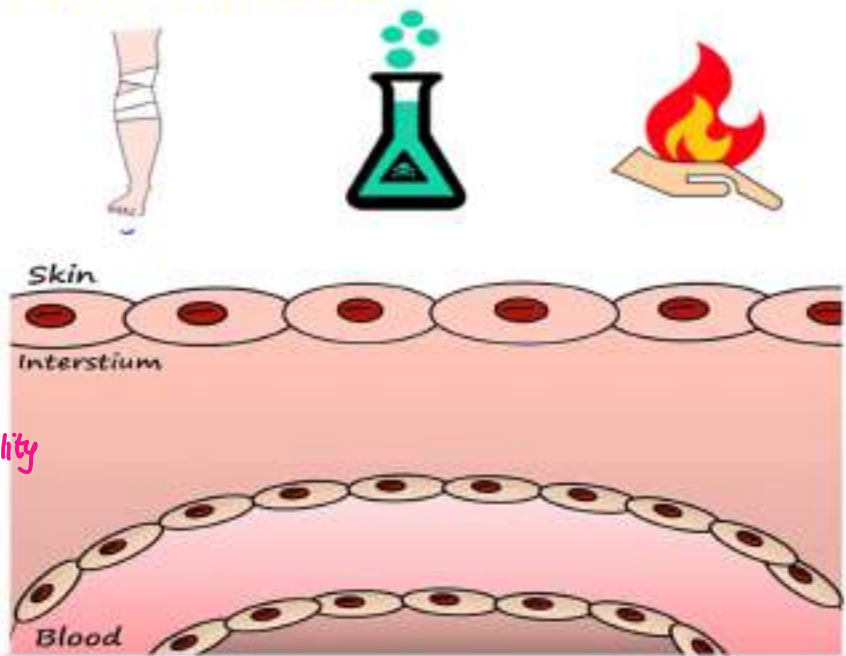

- Hydrostatic pressure is the pressure exerted by a fluid at rest due to the force of gravity.
- Blood pressure is the primary driver of hydrostatic pressure in the capillaries. When blood pressure rises, it increases the capillary's hydrostatic pressure, pushing more fluid into the interstitial space (space between cells) (affects Hydrostatic pressure at the arterial blood of the capillary).
- Conditions in which there is an increase in Blood pressure: Excessive kidney <sup>حفظ</sup> retention of salt and water, Acute or chronic kidney failure.
- Changes in venous pressure also affect Hydrostatic pressure (at the venous end of the capillary).
- Examples for the increased Venous pressure: Heart failure, Venous obstruction <sup>انسداد الأوعية الدموية</sup>

## Edema: Causes

### 2- The permeability of the capillary (Represented by K).

- ✓ Physical trauma → *دخ*
- ✓ Toxins
- ✓ Burn
- ✓ Inflammation

*Histamine* → contraction of endothelial cells & this will increase permeability

- Sinusoidal capillaries have high permeability (high 'k') due to their larger fenestrations and gaps between cells.
- Tight capillaries have a low permeability (low 'k') because they have fewer and smaller fenestrations.
- The permeability 'k' can change due to various factors.
- An example of such a change: Inflammation, burn, and Toxins.
- **Inflammation → Release of Histamine → Endothelial Contraction → Edema**

## Edema: Causes

---

### 3- Decreased capillary oncotic pressure:

- Oncotic pressure is a form of osmotic pressure exerted by proteins, mainly albumin, in the capillary.
- Conditions that decrease protein concentration in the body lead to decreased capillary oncotic pressure.
- Examples:
  - Loss of protein from denuded skin areas (Burns, wounds). مكشوف
  - Loss of proteins in urine (nephrotic syndrome)
  - Failure to produce proteins (liver disease (e.g., cirrhosis).
  - Serious protein or caloric malnutrition.

# Edema: Causes

## 4- Lymphatic system blockage or breakdown

Conditions:

Removal or irradiation of lymph nodes (cancer).

Parasitic infection of lymph nodes

استغناء

طفيلي

lymphedema of the left arm after mastectomy (surgical removal of the breast) and axillary lymphadenectomy (surgical removal of the axillary L.N)

Peri-orbital edema due to inflammation/insects/trauma

The abdomen of a person with cirrhosis that has resulted in massive ascites

تكدف الكبد

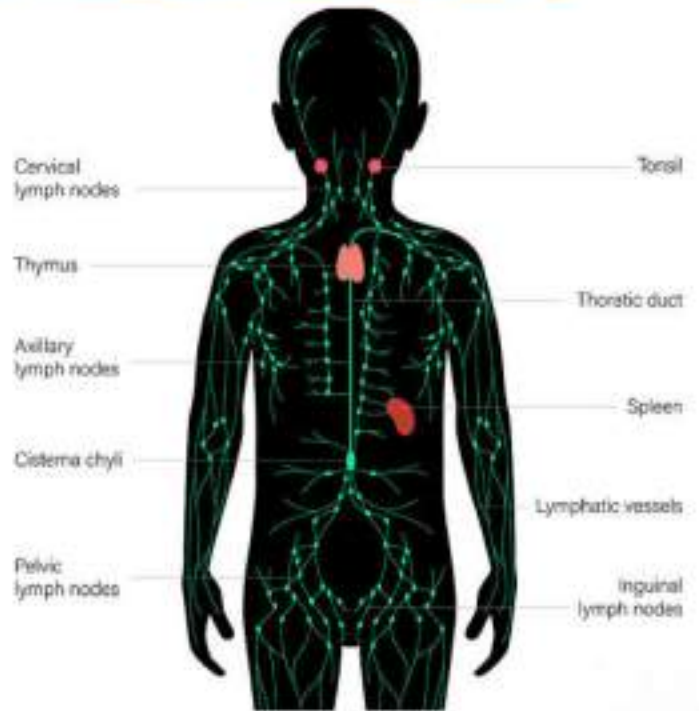

Edema due to heart failure

## Lymphatic System:

### Components:

- 1- Lymph
- 2- Lymphatic Vessels
- 3- Lymphatic organs
- 4- Lymph Nodes

### 1- Lymph:

- Lymph is a fluid similar to blood plasma (It's derived from blood plasma).
- Accumulated interstitial fluid is picked up by lymphatic vessels.
- Once inside the lymph capillaries, the fluid is called lymph.
- Returning this fluid to the blood prevents edema.
- This process helps maintain normal blood volume and pressure.

الوزن من الماء

### 2- Lymphatic organs (thymus, spleen, tonsils and bone marrow):

- Lymphatic organs contain clusters of lymphocytes and other cells like macrophages.
- When the body is exposed to foreign substances, lymphocytes proliferate in these organs.
- These lymphocytes are then dispatched to the invasion site via the blood.
- This is part of the immune response aimed at destroying the invading agent.

## Lymphatic System:

### ➤ Components of the Lymphatic System

#### 3- Lymph Nodes:

- Lymph nodes: small, bean-shaped structures in the lymphatic system.
- Distributed throughout the body along lymphatic vessels.
- Function as filters for lymph, removing harmful substances.
- Lymph nodes are key sites for the initiation of the immune response.

#### 4- Lymphatic Vessels:

- Lymphatic vessels only carry fluid away from tissues.
- The smallest vessels are lymph capillaries, which start as blind-ended sacs in tissue spaces.
- The capillary wall is composed of overlapping endothelium forming a one-way valve.
- This permits fluid entry but prevents lymph from leaving the vessel.

بهاية كغولتو غور وامنحه

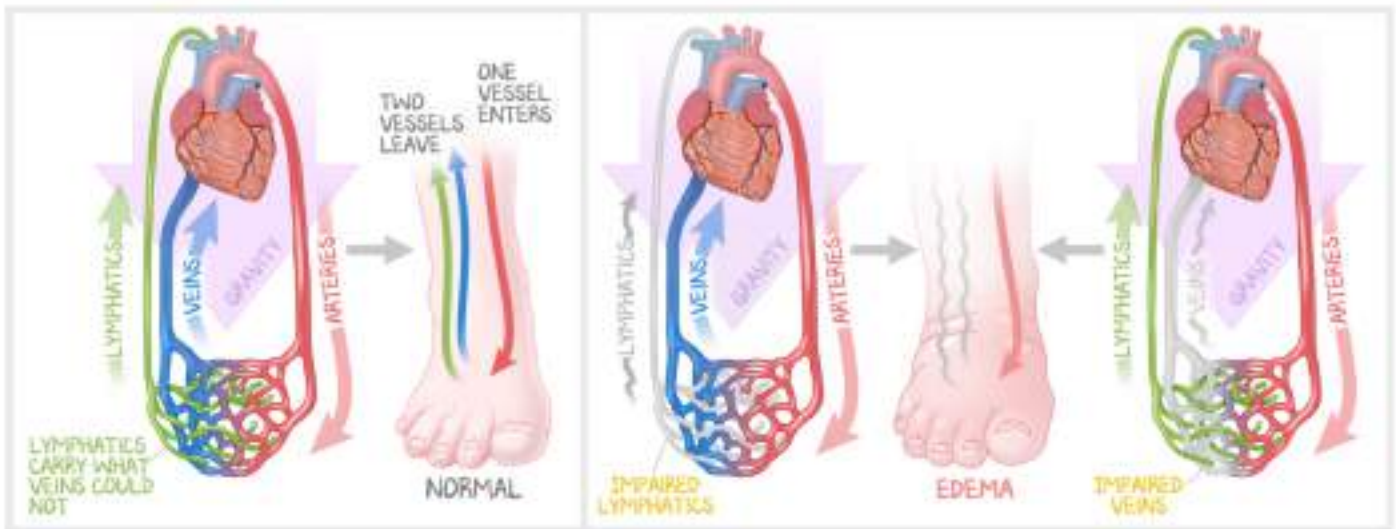

## Lymphatic Vessels:

- Lymphatic vessels begin as lymphatic capillaries, which are closed on one end.
  - Lymphatic capillaries are close to vascular capillaries within the interstitial fluid.
  - These capillaries have one-way flap valves, allowing entry but not exit of interstitial fluid and protein.
- 
- The edge of one endothelial cell overlaps with an adjacent cell, creating a flap that forms a minute valve.
  - This valve opens inward to the lymphatic capillary, allowing interstitial fluid and suspended particles to enter.
  - Backflow is prevented as it causes the flap valve to close, stopping the fluid from leaving the capillary.

### Fluid in is Arterial, while Fluid Out Is Both Veins and Lymphatics

## Lymphatic System Functions: Summary

---

**1. Immunity:** The lymphatic system plays a major role in the body's immune response. It produces, stores, and carries white blood cells, particularly lymphocytes, which protect the body against infection and disease.

**2. Fluid Balance:** It helps maintain fluid balance in the body by collecting excess fluid and particles from tissues and returning them to the blood.

**3. Absorption of Dietary Fats:** The lymphatic system in the small intestine absorbs dietary fats that are not directly taken up by the bloodstream.

**4. Filtration:** The lymph nodes filter lymph, a fluid containing white blood cells, to remove bacteria, viruses, and other foreign particles.

**5. An accessory route** by which fluid and protein can flow from interstitial spaces to the blood
