• Cancer cells are cells that lose their ability to divide in a controlled way

- Normal cell division is controlled by genes
- <u>Cancers</u> are caused by **damage to these genes**
 - Damage usually happens during lifetime
 - Or can occasionally be *inherited*
- Cancer is a disease that starts in the genes.

- For cancer to grow bigger than pin head, it must grow its own blood vessels (angiogenesis)
- Sometimes, cells move away from original (primary site) and spread to other local/ regional sites due to secretion of proteases → metastasis

2. Tumour suppressor genes (P53) \rightarrow In next lecture

Proto-oncogenes & Oncogenes

مسوؤلين عن division /growth الع

Proto-oncogenes are genes that are present in normal cells and their products play important role in normal cell differentiation (normal cell growth).

ex: EZF • They include growth factors, growth factor receptors, signal transduction proteins, transcription factors.

• There are normally about 100 types of proto-oncogenes in each human cell which participate in the regulation of normal cell growth.

Oncogenes are altered proto-oncogenes that encode proteins capable of causing cancer.

هي جينات ستح بروتينات تسب (Cancer م

Extreme cell division

(extreme silly growth)

Mechanisms for conversion of proto-oncogenes to oncogenes

Point mutation in proto-oncogene 1.

Normal protein, that is just over express overexpressed (basically too much of normal protein) - بير الملك دوا والمسل Gene amplification & overexpression of its' protein products 2. Alteration (mutabian) - a ge and a de an an an an a

- Chromosomal translocation 3.
- Insert mutagenesis (viral carcinogenesis) 4.

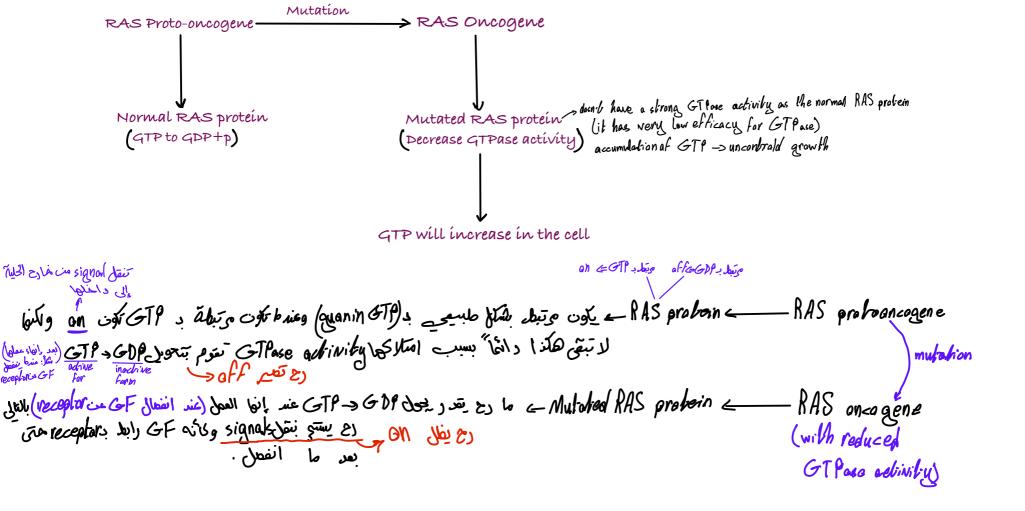

I. Point mutation in proto-oncogene

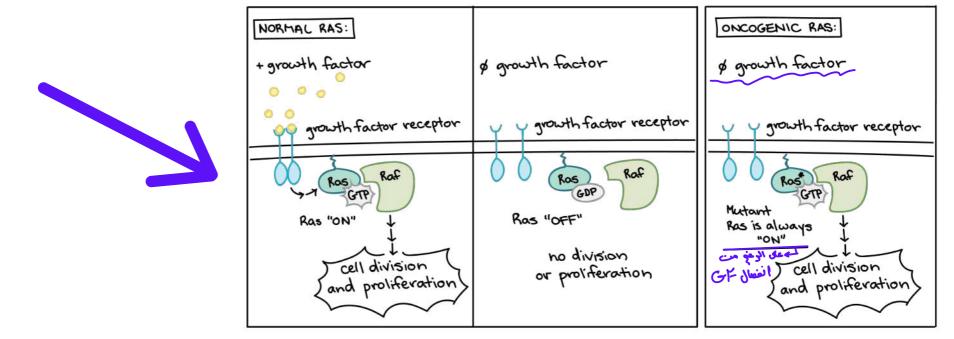

Point mutations

- This produces changes in the protein product of the gene.
- The **Ras oncogene** represents the best example of activation by point mutations.
- G-probeins able als of
 - Ras protein, the product of the Ras proto-oncogene, is a class of G protein that is found in all nucleated cells.
 - It has an **intrinsic GTPase activity**.

hydrolysis of GTP a, P, Y <u>3 subunits</u> hydrolysis of GTP a, P, Y has GTPale advivity of GTP - GDP+P tive Form

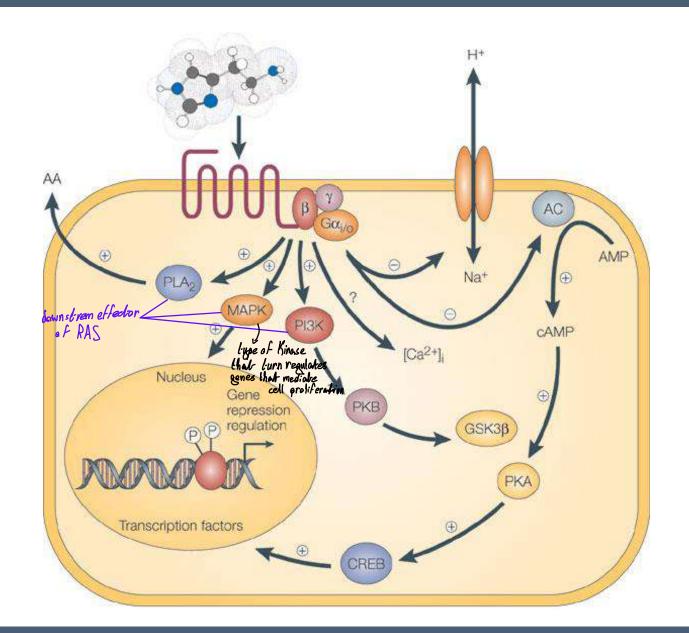

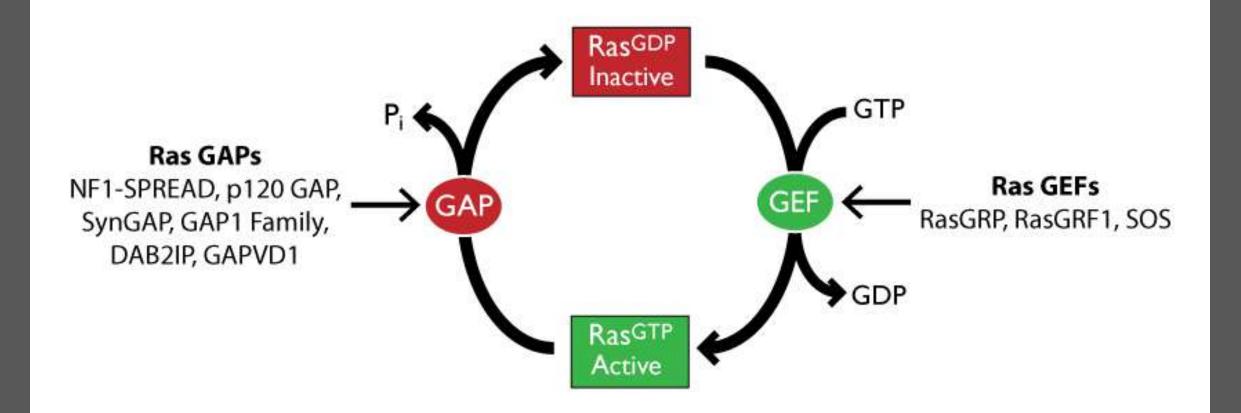

Ras is a G protein, meaning that it switches back and forth between an inactive form (bound to the small molecule GDP) and an active form (bound to the similar molecule GTP). Cancer-causing mutations often change Ras's structure so that it can no longer switch to its inactive form, or can do so only very slowly, leaving the protein stuck in the "on" state (see cartoon above)

I. Point mutation in proto-oncogene

مع بيكون رابط به GTP

- G proteins also known as *guanine nucleotide binding proteins*. A family of proteins that act as molecular switches inside cells and are involved in transmitting signals from a variety of stimuli outside a cell to its interior.
- When they are bound to GTP, they are 'on' → turn on genes involved in cell growth/ replication, differentiation, survival
- When they are **bound to GDP**, they are **'off'** → **inhibit above functions**

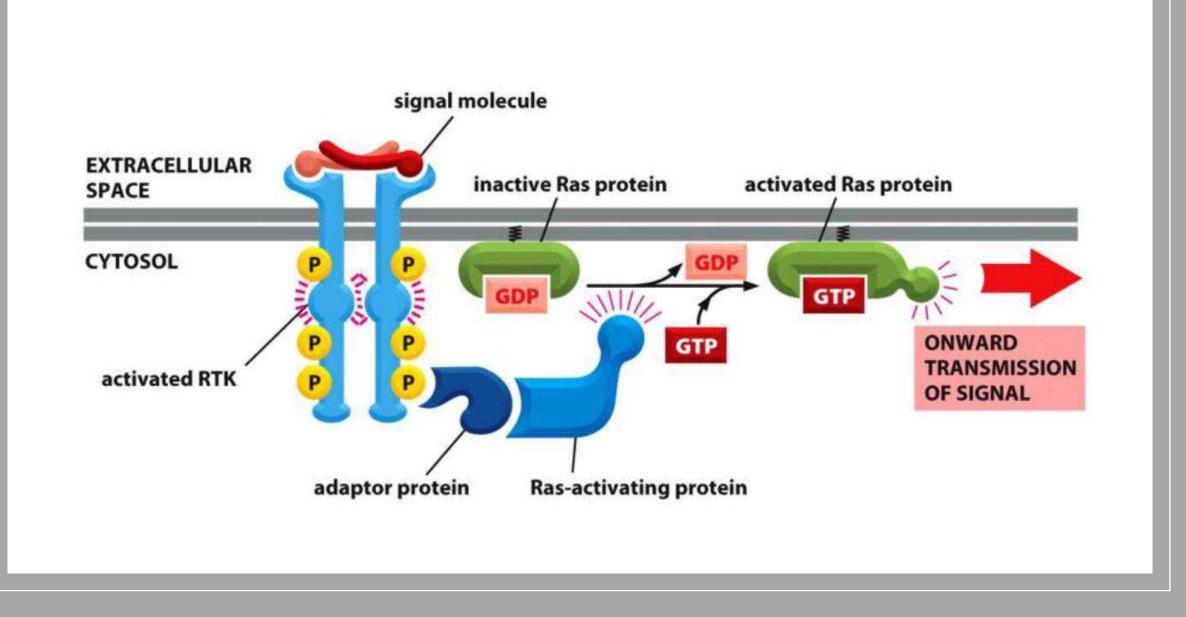

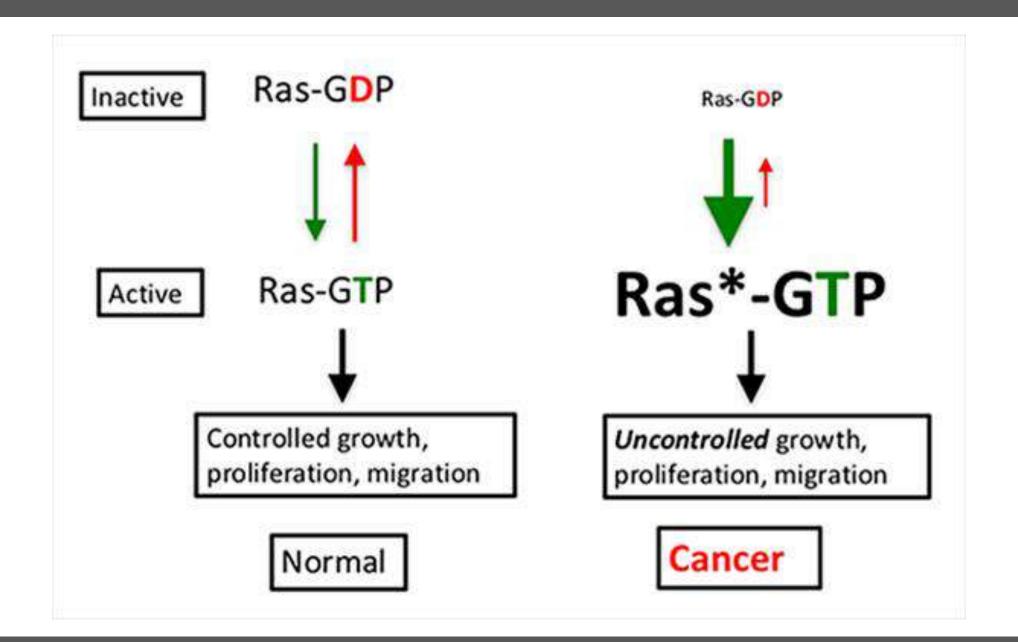

I. Point mutation in proto-oncogene

• Point mutation converts this gene into <u>Ras oncogene</u> with <u>reduced</u> GTPase activity.

- Thus, the effect of growth factors acting through G protein continues after the growth factor dissociates from the receptor.
 - This mutation is observed in about 15% of cancers.
 mutation ما يرله RAS protoon cagene بنلاف محص عنده معنده randial and an cancer or bladder cancer and and a second a second and a second a second a second a second and a second a second and a second a seco
- In summary: mutated Ras **remains in the active form** (Ras GTP complex) as this point mutation dramatically **reduces the GTPase activity** of the Ras proteins.
 - So mutated Ras acts as a growth promoting signal even in the absence of growth factors.

ے عملية نقل proto an cagene إلى كومو اوم آخر وربعبے تحت رحمة *Promation و*ما م بحين آخر (هذا انجيت بعبيعته يحصل الم transcription بلكلا كبير و بالتابي لأنه العبج تحت مطره محمد معنى الخاص بعدا الحين فإن له مسيسل المنا transcription بنفه العمد في الخاص بعد الحين فإن له مسيسل المنا العد المعد في

Placing the **normal proto-oncogene** <u>**near the promotor**</u> (stimulate transcription) of another gene with subsequent overexpression of this proto-oncogene.

e.g. c-MYC in lymphoid tumors (Burkitt lymphoma).

increase orofo-oncogene. • MYC (c-MYC) is a regulator gene that codes for a transcription factor. (induces cell proliferation) The protein encoded by this gene is a multifunctional, nuclear phosphoprotein that plays a role in cell cycle progression and apoptosis.

• In the human genome, MYC is **located on chromosome 8** and is believed to regulate expression of 15% of all genes.

MYC activation results in numerous biological effects.

in nexplecture 1. The first to be discovered was its capability to drive cell proliferation (upregulates cyclins, downregulates p21).

- - It also plays a very important role in **regulating cell growth** (upregulates ribosomal RNA and proteins), **differentiation**, and **stem cell self renewal**. 2.
 - Myc is a very strong proto-oncogene, and it is very often found to be upregulated in many types of cancers.

Chimeric protein. Fusion proteins or chimeric proteins are proteins created through the joining of two or more genes

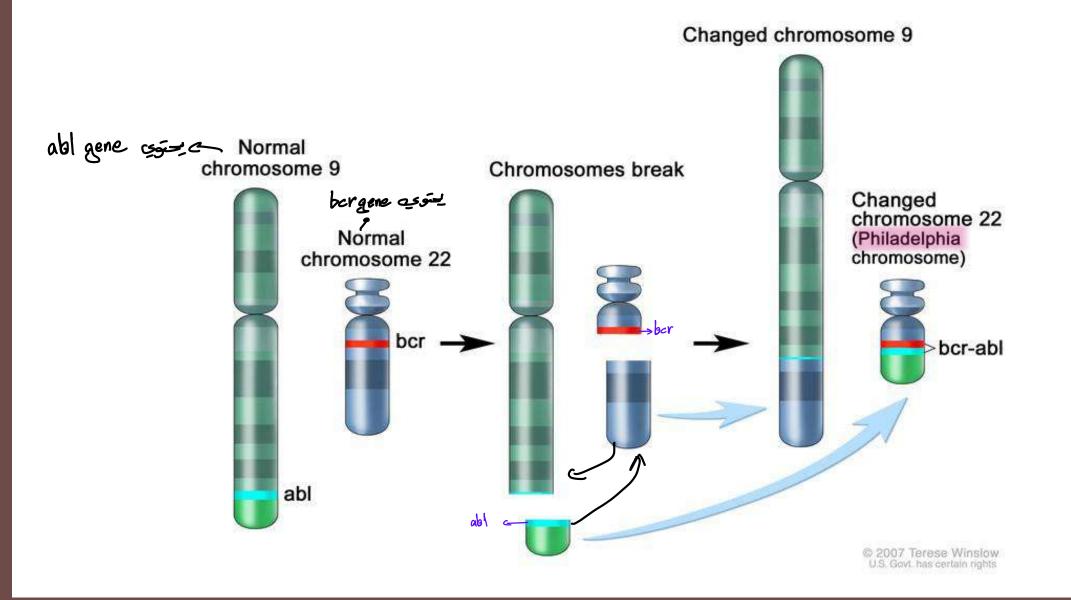

> 2. Placing **normal unaltered genes** from **two different chromosomes** to **recombine** and form hybrid genes that **encode growth promoting** kulic (chimeric) proteins.

• e.g. Philadelphia chromosome.

 The Philadelphia chromosome or Philadelphia translocation is a specific genetic abnormality in chromosome 22 of leukemia cancer cells (particularly chronic myelogenous leukemia (CML) cells).

This chromosome is defective and unusually short because of reciprocal translocation of genetic material between chromosome 9 and chromosome 22, and contains a fusion gene called BCR-ABL1 coding for a hybrid protein.
 It results in cyclins is in the coding for a hybrid protein.

A tyrosine kinase signaling protein that is "always on", causing the cell to divide uncontrollably.

III.Gene Amplification

growth constants on genes a unit of products on a units of and growth lange a of the products of the product • Such amplification may produce several hundred copies of the proto-oncogene in the tumor cell

e.g. c-erb B2 in breast cancer; also frequently called HER2 (from human epidermal growth factor receptor 2 and encoded by ERBB2 gene) in breast cancer -> ave rexpressed ~ the disease has a poor prognosis - overexpression of HERZ ويتكون عندها breast cancer on prognosis - overexpression of HERZ ويتكون عندها

• It encodes a transmembrane protein with tyrosine kinase activity

Tyrosine kinases are important mediators of this signal transduction process, leading to cell proliferation, differentiation, migration, metabolism.

• The over expression of the ERBB2 gene, occurs in approximately 15-30% of breast cancers. It is strongly associated with increased disease recurrence and a poor prognosis.

Leads to uncontrollable division of cell receptors se iles interestors

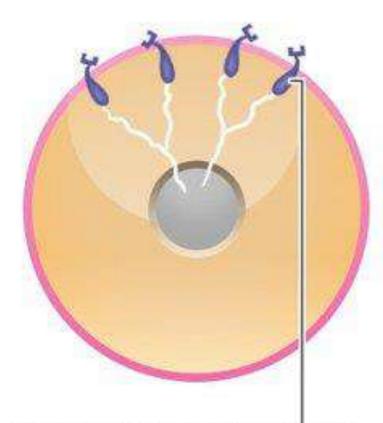

on cogene at the and it amplification of probo on cogene

III.Gene Amplification

• In summary, signaling through the ErbB family of receptors promotes cell proliferation and opposes apoptosis, and therefore must be tightly regulated to prevent uncontrolled cell growth from occurring. dihydrofalate reductose, فالمعلمة المالة والله المعلمة المحلية التلخي المعناية العن التزيج • Dihydrofolate reductase gene is amplified in cancer patients (acquired methotrexate

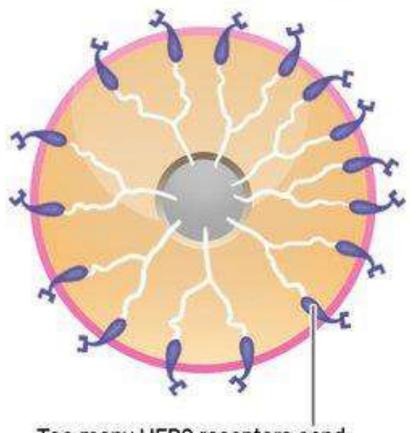

resistance) receiving methotrexate, an inhibitor of the dihydrofolate reductase enzyme.

Normal breast cell

Normal amount of HER2 receptors send signals telling cells to grow and divide.

Abnormal HER2+ breast cancer cell

Too many HER2 receptors send more signals, causing cells to grow too quickly.

Retrovirus----RNA virus

virul cDNA host-DNA

protooncogene

1. Retrovirus transduction:

When a retrovirus infects a cell, its RNA genome synthesizes a complementary DNA (cDNA) inside the infected host cell by the viral encoded RNA-dependent DNA polymerase (reverse transcriptase).

cancer use incorporation vibin DNA of hast cell user Wirul DNA user with out of hast wire wirul DNA

The viral cDNA then integrates into the genome of the host cell where it can be copied as the host genome is duplicated during the process of cellular division. عداع يهمي الما والمعام بيكون موجود بالعدفة Virul gename incarparation بيعيرك hostraenome في عنه Virul gename في incarparation الأناد هذه العطلية بمزة من محفظ ومعامي المناد هذه العطلية بمزة والمعالية عن تأثر والمعالية المناد المعالية المراد المعالية المحفظة المراد المعالية المراد المعالية المحفظة المراد المعالية المراد المحفظة المحفظة المحفظة المراد المعالية المحفظة المحفظة المحفظة المحفظة المعالية المحفظة المح

- At the ends of the retroviral genome there are powerful transcriptional promotor sequences termed **long terminal repeats** (LTRs).
 - The LTRs promote the transcription of the viral DNA leading to the production of new virus particles (viral RNA genome)

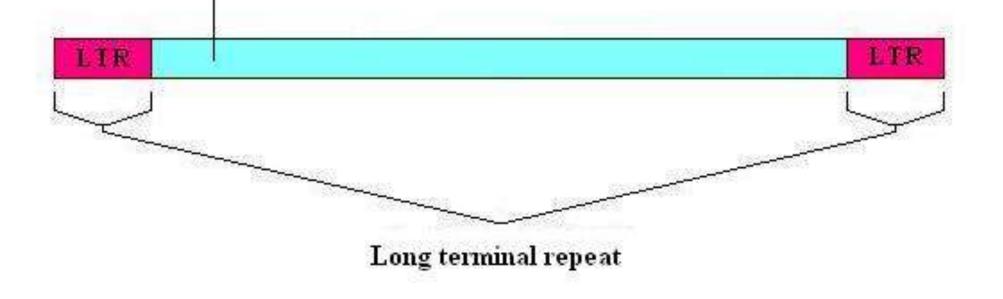

معرفول من normal coll growth منع تيم ترجمته السكل حبير والتالي يودي الى concer

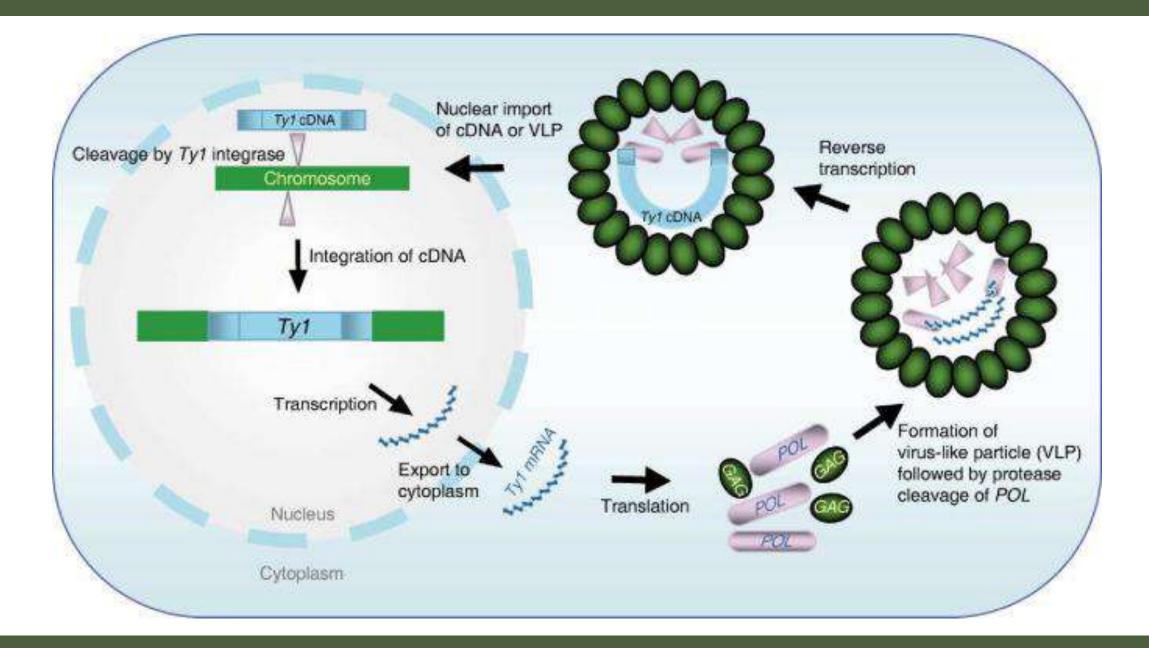

- Occasionally, the virus carries a portion of host DNA. Subsequent infection of a new host by such a virus may introduce new genes to the new host
 - This process is termed transduction.
 Incorporation of a protein of host genome into the viral genome

- Occasionally this transduction process leads to the virus acquiring a gene from the host that is normally involved in **cellular growth control.**
- This gene will be transcribed at a higher rate due to its association with the retroviral LTRs → the transduced gene stimulates the growth of the infected cell.
- The end result of this process is **unrestricted cellular proliferation** leading to tumorigenesis (cancer formation).

LTR Transposon

Genes for transposition

2. Retrovirus integration:

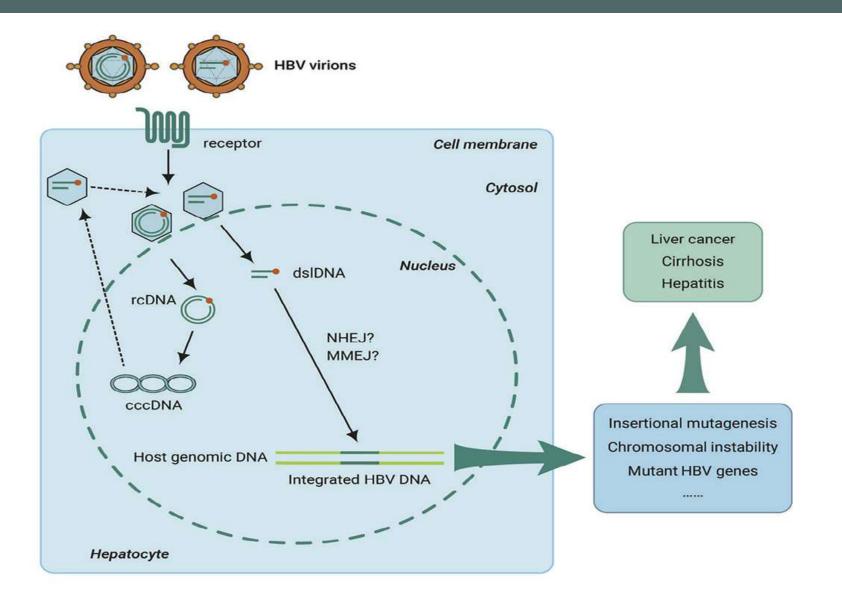

• The second mechanism by which viruses can transform cells <u>relates to the</u> <u>powerful transcription promoting effect of the LTRs.</u>

protoon cogene بدون ما يعير protoon cogene incorporation into the vivul genom بدون ما يعير protoon cogene فعار تحت تأثير promotor

- When a virus genome integrates into a host genome it does so randomly
 This is called virus integration
 - This is called **virus integration**.
- Sometimes, this integration process leads to the placement of the LTRs close to a gene that encodes a growth regulating protein.

- If the protein is expressed at an abnormally elevated level it can result in cancer development.
- A notable example is the integration of hepatitis B virus genome (DNA virus) into the hepatocyte genome leading to induction of liver cancer.
- **HIV (human immunodeficiency virus)** induces certain forms of cancers in infected individuals by this integration induced transformation process.

- Unlike retroviruses, genomic integration has no role in HBV replication.
- Integrated viral DNA is found in 85%-90% of HBV-related HCCs (hepatocellular carcinoma) and its presence in tumors from noncirrhotic livers of children or young adults further supports the role of viral DNA integration in hepatocarcinogenesis.
- A significant feature of chronic HBV infection is that HBV DNA fragments are integrated into different locations within the host DNA.

Questions:

- The Philadelphia chromosome, commonly associated with leukemia, results from a translocation involving which two chromosomes?
- a) 9 and 10 22
- b) 11 and 22
- c) 13 and 14
- d) 17 and 18

Questions:

• Which genetic alteration is commonly associated with chronic myeloid leukemia (CML)?

Answer: A

- a) BCR-ABL fusion gene
- b) BRCA1 mutation
- c) HER2 amplification
- d) HBV integration

Questions:

- What is the primary role of oncogenes in cancer development?
- a) Repair damaged DNA
- b) Promote cell division and growth
- c) Inhibit cell cycle progression
- d) Suppress tumor formation
